

COMP1021  
Introduction to Computer Science

# Beginning to Program Python

David Rossiter

# Outcomes

- After completing this presentation, you are expected to be able to:
  1. Run one line of code at a time in the shell
  2. Run several lines of code as a program
  3. Use code to do simple text input and output
  4. Use variables to store things, such as text and numbers

Best match

 IDLE (Python 3.10 64-bit)  
App

# How to Run Python?

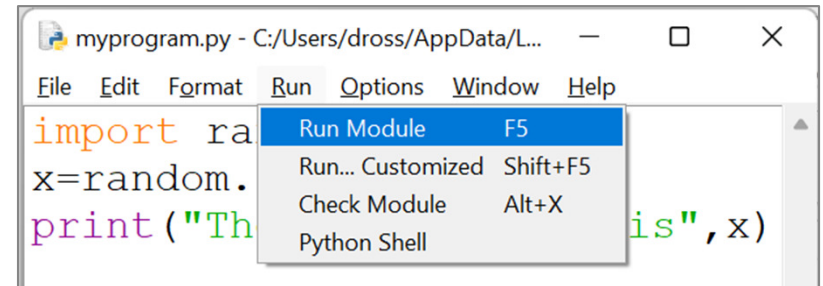

- We will talk about two approaches:

1. You run Python  
code in the *shell*

2. You run Python  
code in a *program*

```
IDLE Shell 3.10.4
File Edit Shell Debug Options Window Help
Python 3.10.4 (tags/v3.10.4:9c3d1e1, Nov 23:13:41) [MSC v.1929 64 bit
Type "help", "copyright", "credits" or "help()" for more information.
>>> print("Today is a hot day!")
```

```
myprogram.py - C:/Users/dross/AppData/L...
File Edit Format Run Options Window Help
import random
x=random.random()
print("The number is", x)
```

See the last slide

In the world of computers, a *shell* means  
a place where you run one line of code, then  
you see the result of running that line of code

# Input and Output

- In this presentation we'll look at text input
- Later we will look at handling some other types of input such as mouse input
- In this presentation we'll look at text output
- Later we'll look at some other types of output such as graphics output and music output

# Text Output

- Let's do some simple text output
- Here is a line of Python code which shows a message on the screen:

```
print("Today is a hot day!")
```

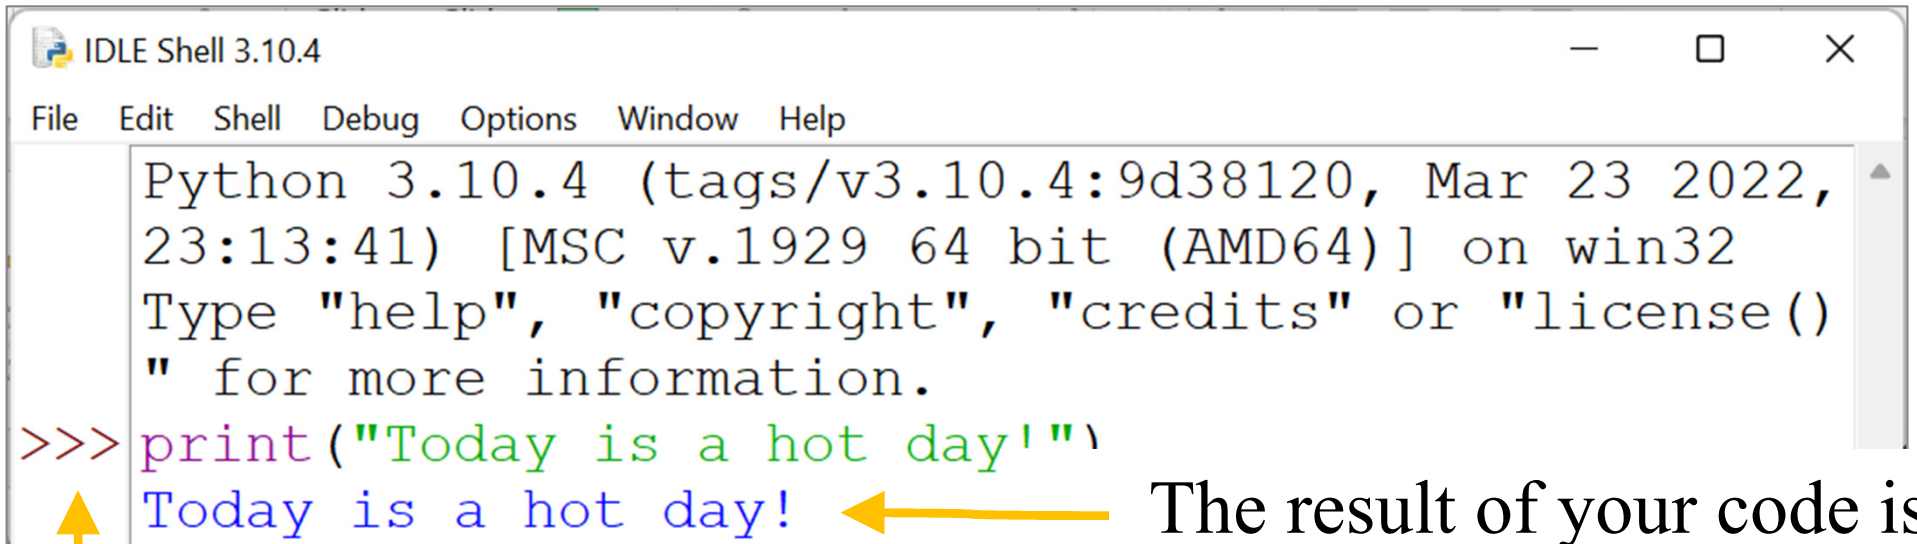

- This is the print command that asks Python to show something on the screen
- You put the message you want to show inside a pair of parentheses, i.e. ( )
- This is the message that we want to show on the screen
- When you use text in code, you need to enclose the text using a pair of quotes, " " or ' '

Best match

 IDLE (Python 3.10 64-bit)  
App

# Using the Shell

- When you start IDLE you see the shell
- If you type the code into the shell then press Enter, the code is given to the interpreter and the result is shown:

```
Python 3.10.4 (tags/v3.10.4:9d38120, Mar 23 2022,
23:13:41) [MSC v.1929 64 bit (AMD64)] on win32
Type "help", "copyright", "credits" or "license()"
for more information.
>>> print("Today is a hot day!")
Today is a hot day!
```

The result of your code is shown here, under the code

>>> means 'next to this is your code'

# Text Input

- Let's do some text input
- Here is a line of Python code which shows a message and lets the user enter something:

```
input("What is your name?")
```

- This is the input command which:
  - asks Python to show something on the screen, and
  - returns whatever the user types
- This is the message that we want to show on the screen

# Remembering Things

- We need a way to remember what the user enters
- To do that we use a *variable*
- You can think of a variable as a box
- When you do

*variable\_name* = input ( ... )

then whatever the user types is stored  
in the box

The >>> means we are using the shell; you can ignore that part

# Using a Variable

"Dave"  
name

- Here is some code which stores any text the user enters in a variable:

```
name = input("What is your name?")
```

```
>>> name = input("What is your name?")  
What is your name?Dave
```

1. *We give the Python interpreter this code*

2. *The Python interpreter executes the code, we see the message*

4. *The Python interpreter stores the input in the variable called 'name'*

3. *The user types in some input*

# Accessing the Variable

- If we want to use whatever is in the variable, we simply use the name of the variable
- For example, let's use `print()` to show what's in the variable:

```
>>> print(name)  
Dave
```

- We could mix it with some text, like this:

```
>>> print("Your name is", name)  
Your name is Dave
```

or this:

```
>>> print("Your name is", name, "and it's a great name!")  
Your name is Dave and it's a great name!
```

# What About Entering Numbers?

- If we want to get a number from the user, we can use the same code `input()`
- However, `input()` always produces text
- The code will crash if you try to treat a variable which has text as if it has a number e.g.:

```
>>> money = input("How much money do you have?")
How much money do you have?100
>>> print(money)
100
>>> moremoney = money + 5
Traceback (most recent call last):
  File "<pyshell#23>", line 1, in <module>
    moremoney = money + 5
TypeError: can only concatenate str (not "int") to str
```

# Converting Text into a Number

- What we can do is to take the input from the user, and then convert it to a number using `int()`
- `int()` means ‘convert this into an integer’
- After it has been converted, you can add, subtract, multiply, etc, the number stored in the variable

```
>>> money = input("How much money do you have?")
How much money do you have?100
>>> print(money)
100
>>> money = int(money)
>>> moremoney = money + 5
>>> print(moremoney)
105
```

Convert the *text* “100”  
into an *integer* 100

# Generating a Random Number

- Sometimes it is useful to ask Python to give you some random numbers
- There are several ways to do that in Python
- One of them is to use the `random.randint()` command
- First, we need to use this code:

```
import random
```

- After this, your code can use lots of commands related to random numbers

# Generating a Random Number

- Then we can use `random.randint()` to generate a random number within a particular range, like this:

```
>>> import random
>>> random.randint(1, 10)
2
>>> random.randint(1, 10)
3
>>> random.randint(1, 10)
9
>>> random.randint(1, 10)
5
>>> random.randint(1, 10)
6
```

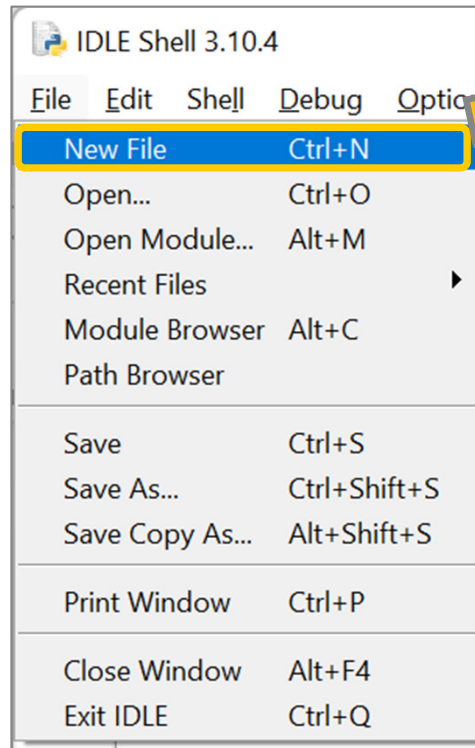

- ← • This says ‘generate a random number which is 1 or 2 or 3 or 4 or 5 or 6 or 7 or 8 or 9 or 10’

- We will use this to generate random numbers later

# Putting Lines of Code Together

- Typing lines of code in the shell is OK but you may want to run the same lines of code many times
- You will go crazy if you have to keep typing them!
- It makes sense to put all the lines of code together into a single file of Python code
- That file, often containing many lines of code, is called a *program*

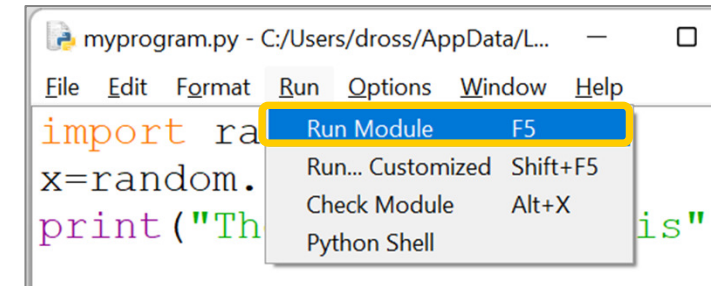

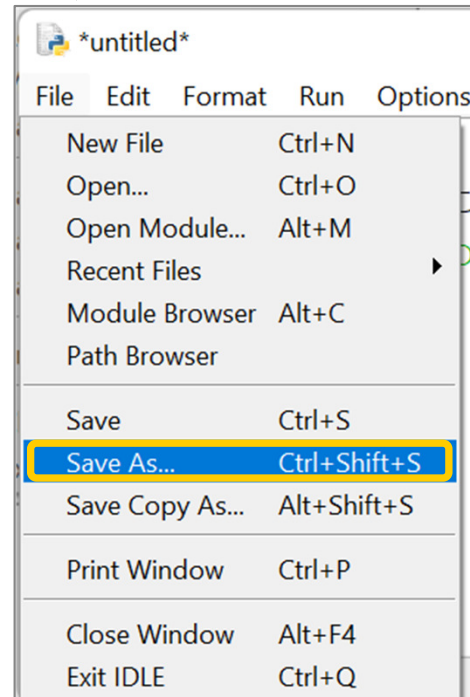

# Making and Running a Program (Windows)

*Create the program*

*Save the program*

*Run the program*

```
= RESTART: C:/Users/dross/AppData/Local/Programs/Python/Python310/Python.exe
The random value is 5
```

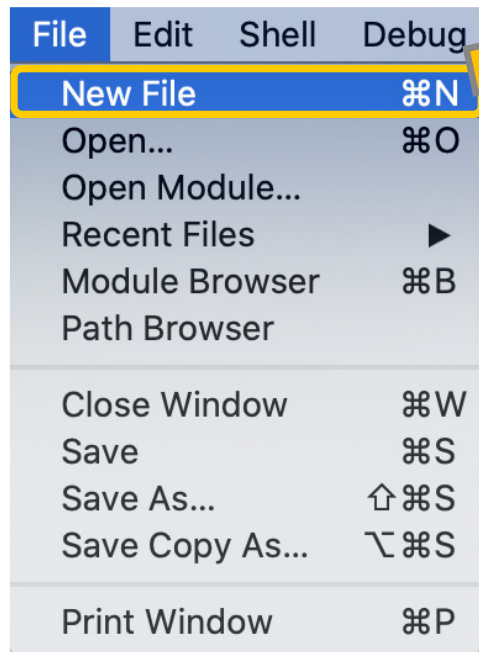

*The result is shown*

- This slide shows IDLE being used on Microsoft Windows

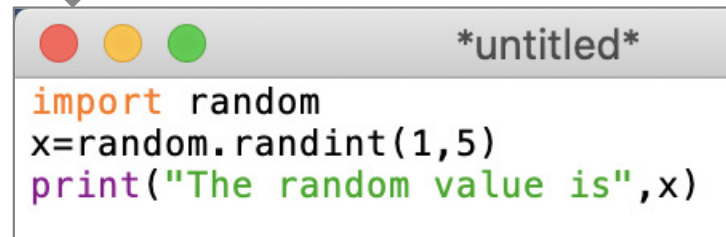

# Making and Running a Program

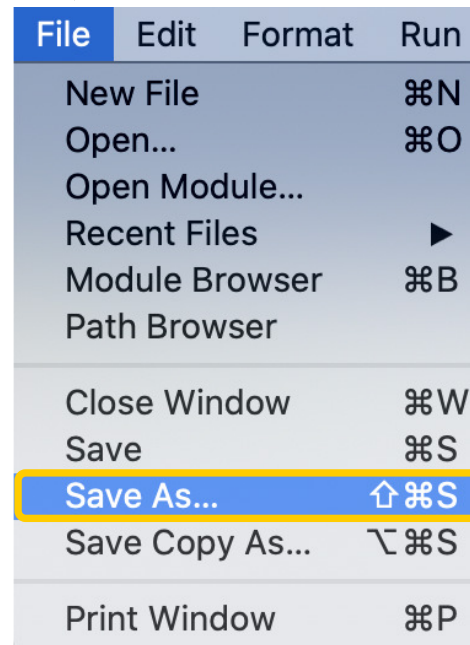

(Mac)

*Create the program*

*Save the program*

*Run the program*

*The result is shown*

- This slide shows IDLE being used on a Mac
